Water Chemistry, Biotic Factors and Their Effects on the Populations of Zooplankton and Phytoplankton in Silver Lake in New Carlisle, Ohio

Jacob Clancy

Advisor: Dr. P. Kelly Williams

Hypotheses

- I hypothesized that Silver Lake would be an oligotrophic (nutrient-poor lake)
- Algal species would differ, and there would be less algal abundance than selected Ohio eutrophic lakes
- Zooplankton would also be less abundant compared to eutrophic Ohio lakes.

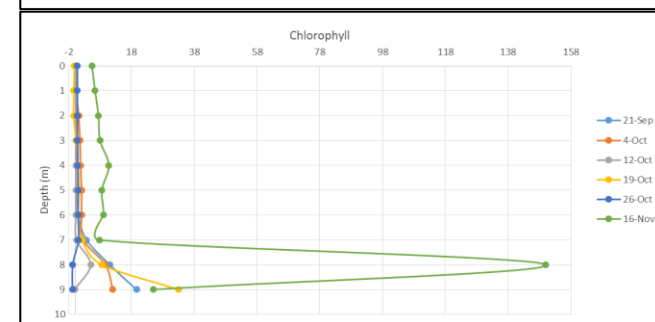

Methods

- YSI 650 MDS electronic equipment for physical and chemical data
- Secchi disk for water clarity
- Qualitative and quantitative plankton nets for organism sampling
- Microscope Analysis

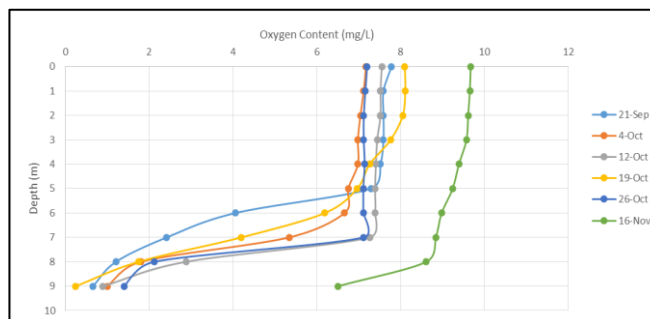

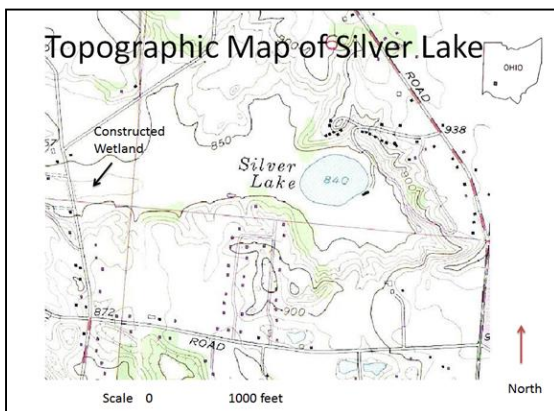

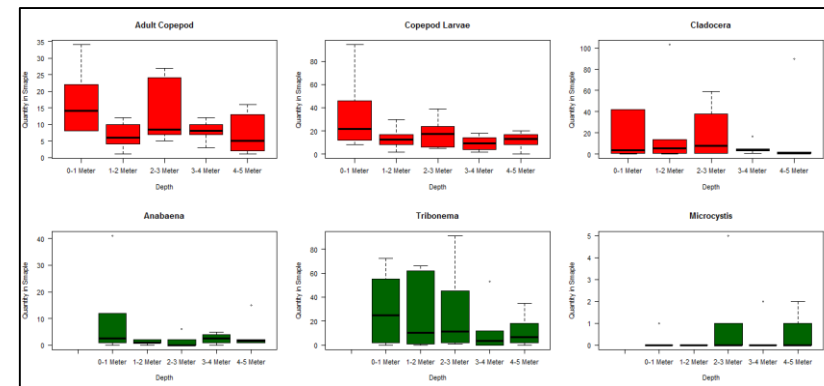

Results

- Silver Lake Secchi Disk depth average was 4.6 meters
- Grand Lake Saint Marys and Lake Erie Secchi Disk depth average was 0.2 meters and 1.5 meters respectively

Geology

- The lake was created by glacial activity.
- This creates springs underneath the lake which fill the lake with water.
- Overflows into constructed wetland.

Conclusions

- Silver Lake is an oligotrophic lake according to its water clarity, chemistry, and plankton abundance
- The algae community in Silver Lake is different from GLSM and Lake Erie
- There were the same zooplankton taxa present in each lake, but the abundance changed over time
